

a Observed colonial-era conditions, by development cluster

One point per country; vertical rule is the cluster median. Dark outline marks the four settler colonies (Australia, Canada, New Zealand, United States). Cluster 2 has no country in the historical sample.

b Fitted ordinal model: expected cluster

Expected cluster with 95% interval, coloniser held at the United Kingdom and the other covariate at its median. Ticks mark observed values; curves are not drawn beyond them. Same vertical scale as panel a.

c Coloniser identity, relative to British colonies

Ordinal coefficients with 95% intervals. Negative = higher-ranked cluster than British colonies at the same settler mortality and 1900 enrolment. Joint likelihood-ratio test: $\chi^2 = 12.45$, $df = 3$, $p = 0.006$.
