

Six improvement regimes, 2000-2020

What each group advanced faster, and slower, than its starting position predicts

● Faster than its starting position predicts ○ Slower than its starting position predicts

Each dot is one of eleven material-provisioning indicators (0-100, higher is better). Improvement rates are ordinary-least-squares slopes on year over 2000-2020, averaged over the 15 multiply-imputed datasets. Each rate is then residualised on a cubic in the country's own year-2000 level of the same indicator, so zero means a regime advanced that component exactly as fast as countries starting from the same position typically did; the plotted value is the regime mean of that residual. This is the space in which the regimes were formed. Table 4 reports the same rates unadjusted, in raw points per year: the two scales disagree in sign for 11 of 66 cells, so they are not interchangeable. Indicators appear in the same order in every panel, grouped by decent-living-standards domain, and all six panels share one horizontal scale. Regimes are ordered by mean development level; the example countries are those at the 12th, 38th, 62nd and 88th percentile of each regime's own level distribution.
